TensorFlow & Deep Learning Malaysia Group

The TensorFlow & Deep Learning Malaysia group's aims are:

- To enable people to create and deploy their own Deep Learning models built using primarily TensorFlow or other Deep Learning libraries.
- To build the key skill sets for this group from the combination of both beginner and intermediate models as well as advancing to the next level
- A knowledge sharing and presentations platform in relation to the cutting edge deep learning research papers and techniques.

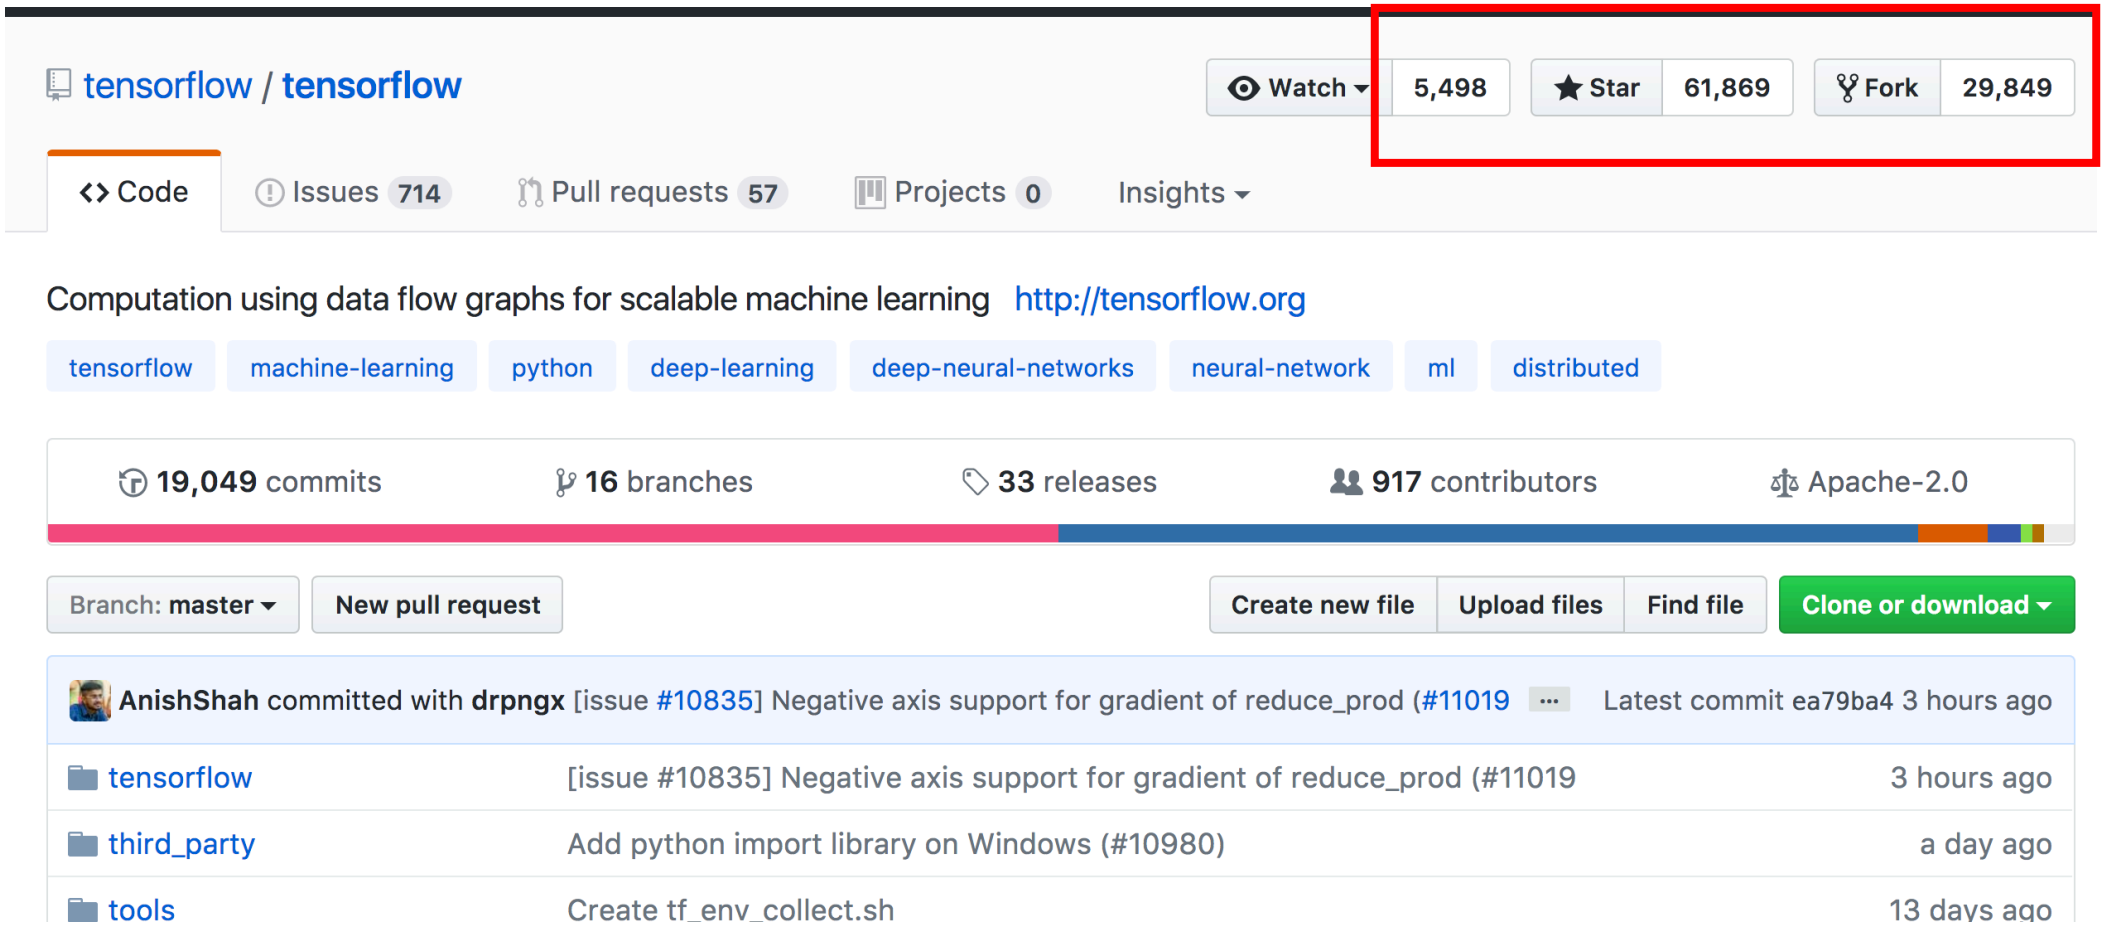
What is TensorFlow?

- URL: https://www.tensorflow.org/
- Released under the open source license on November 9, 2015
- Current version 1.2
- Open source software library for numerical computation using data flow graphs
- Originally developed by Google Brain Team to conduct machine learning and deep neural networks research
- General enough to be applicable in a wide variety of other domains as well
- TensorFlow provides an extensive suite of functions and classes that allow users to build various models from scratch.

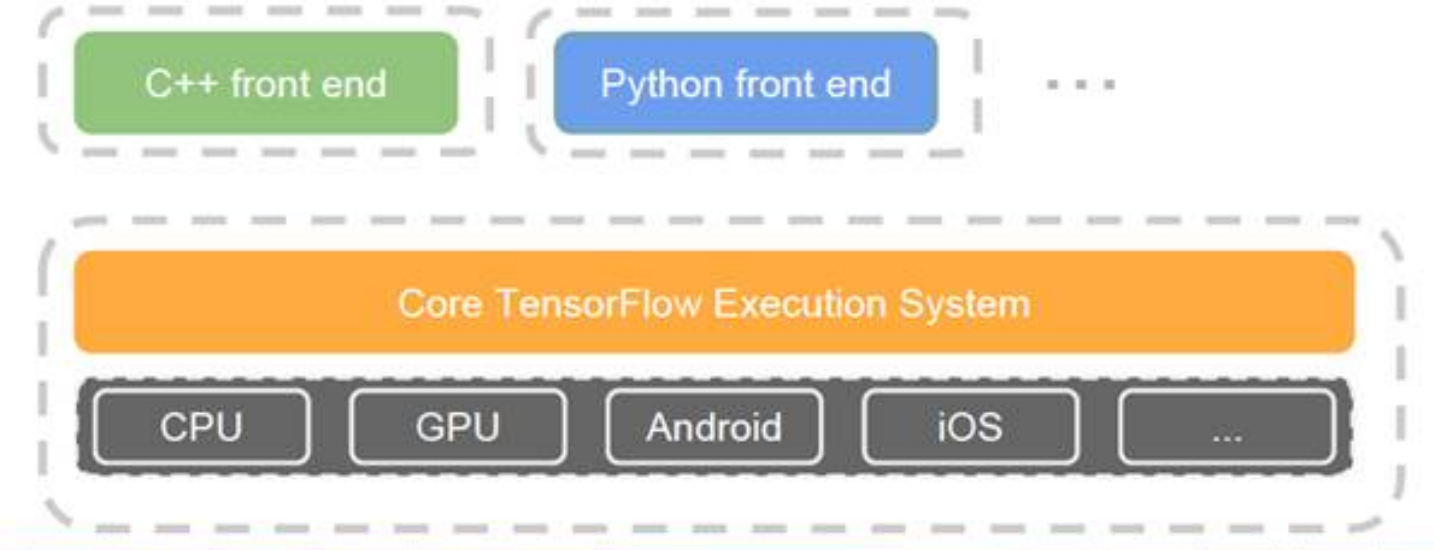
Most popular on Github



https://github.com/tensorflow/tensorflow

TensorFlow architecture

- Core in C++
  - Low overhead
- Different front ends for specifying/driving the computation
  - Python, C++, R and many more



TensorFlow Models

https://github.com/tensorflow/models

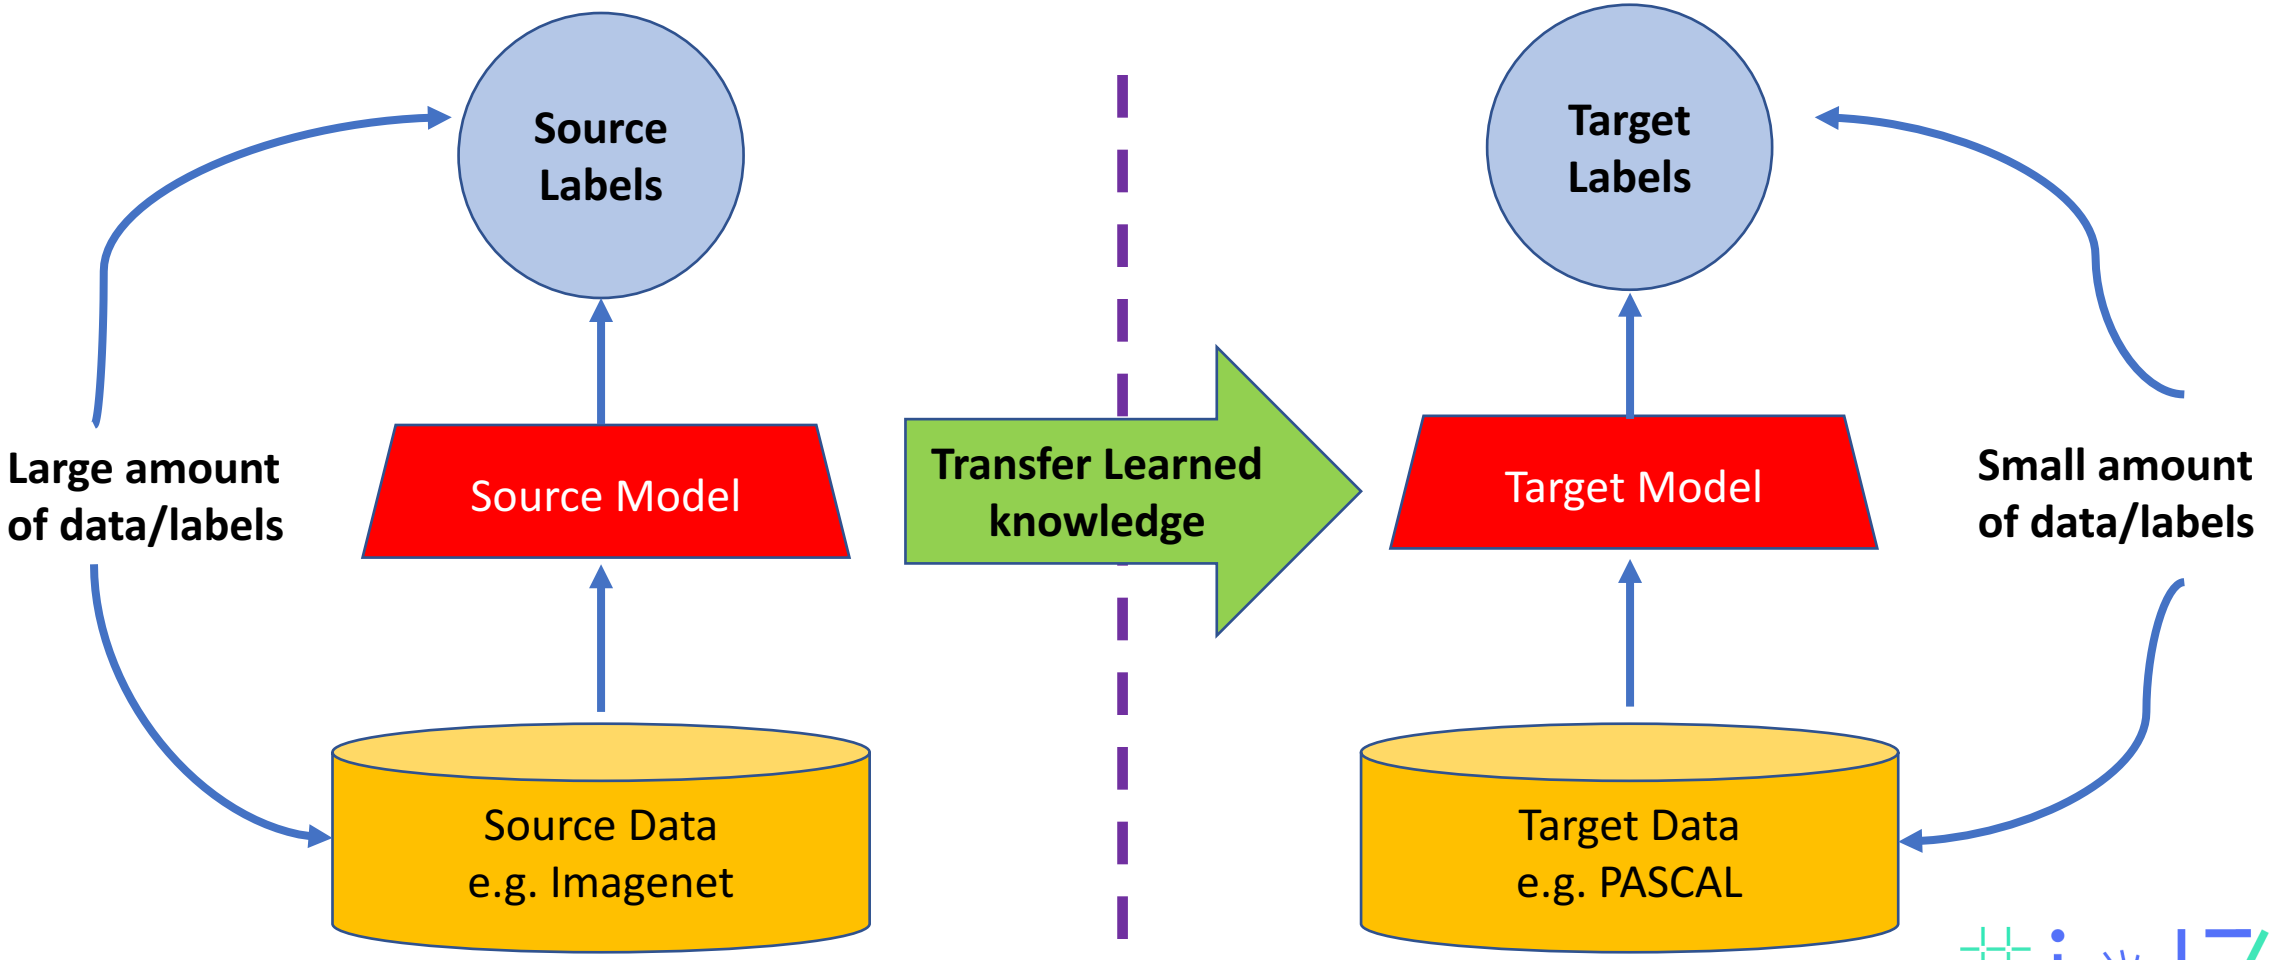
Models

- adversarial_crypto: protecting communications with adversarial neural cryptography.
- adversarial_text: semi-supervised sequence learning with adversarial training.
- attention_ocr: a model for real-world image text extraction.
- autoencoder: various autoencoders.
- cognitive_mapping_and_planning: implementation of a spatial memory based mapping and planning architecture for visual navigation.
- compression: compressing and decompressing images using a pre-trained Residual GRU network.
- differential_privacy: privacy-preserving student models from multiple teachers.
- domain_adaptation: domain separation networks.
- im2txt: image-to-text neural network for image captioning.
- inception: deep convolutional networks for computer vision.

Transfer Learning : Idea

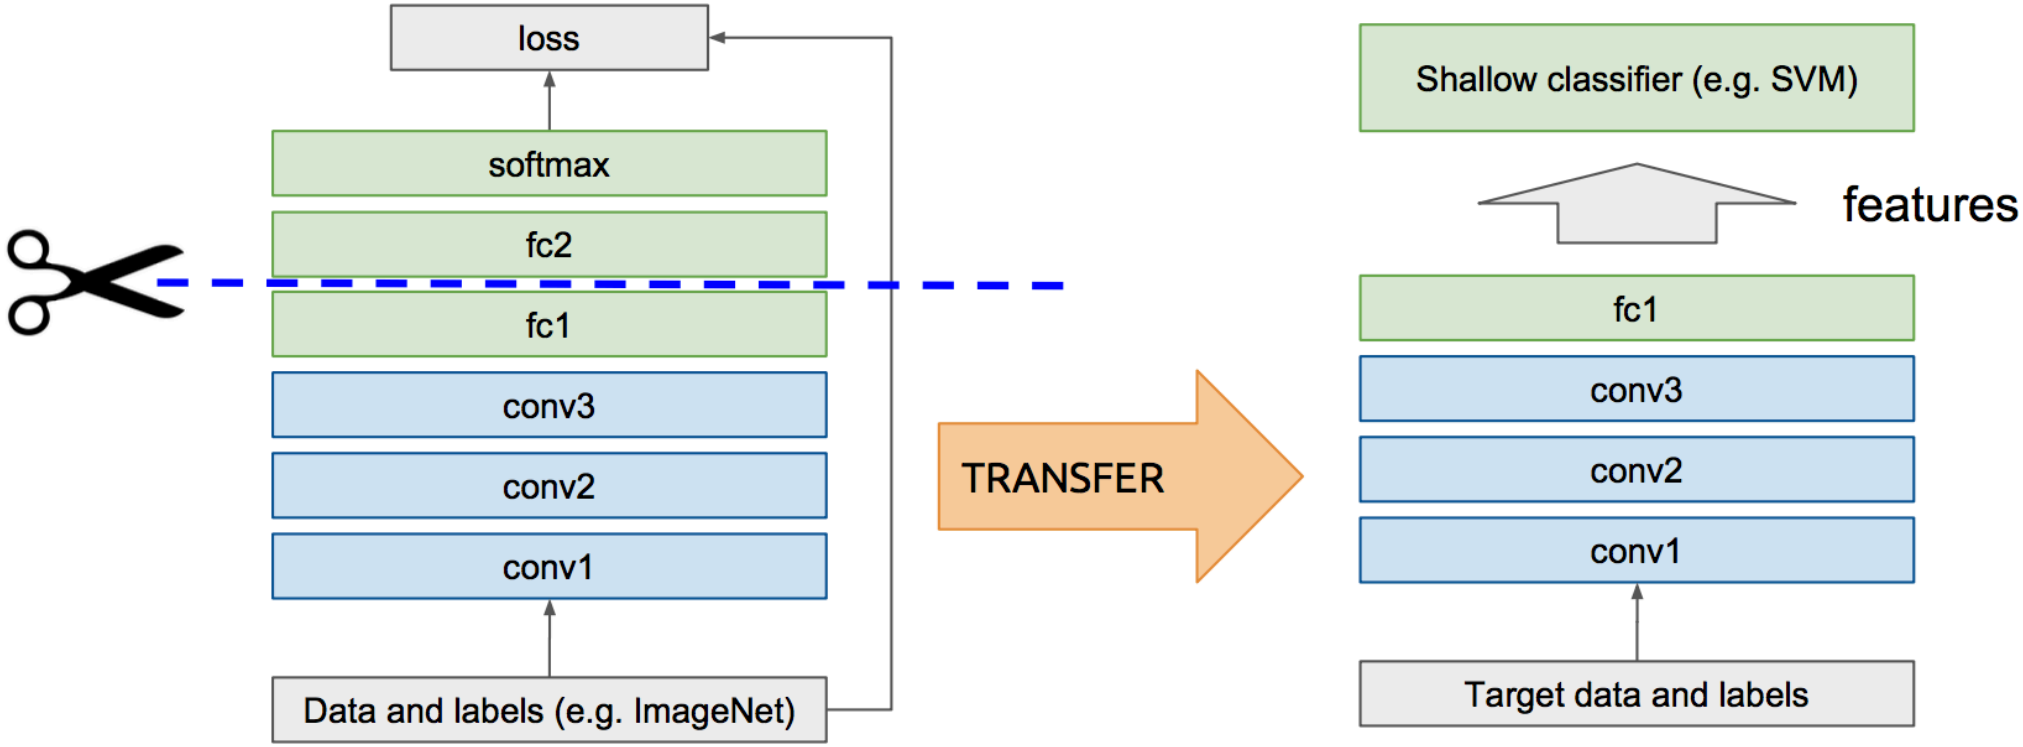
- Instead of training a deep network from scratch for your task:
  - Take a network trained on a different domain for a different **source task**
  - Adapt it for your domain and your **target task**

Transfer Learning: Idea



Off the Shelf

- Idea: use outputs of one or more layers of a network trained on a different task as generic feature detectors. Train a new shallow model on these features.



Why use a pre-trained model?

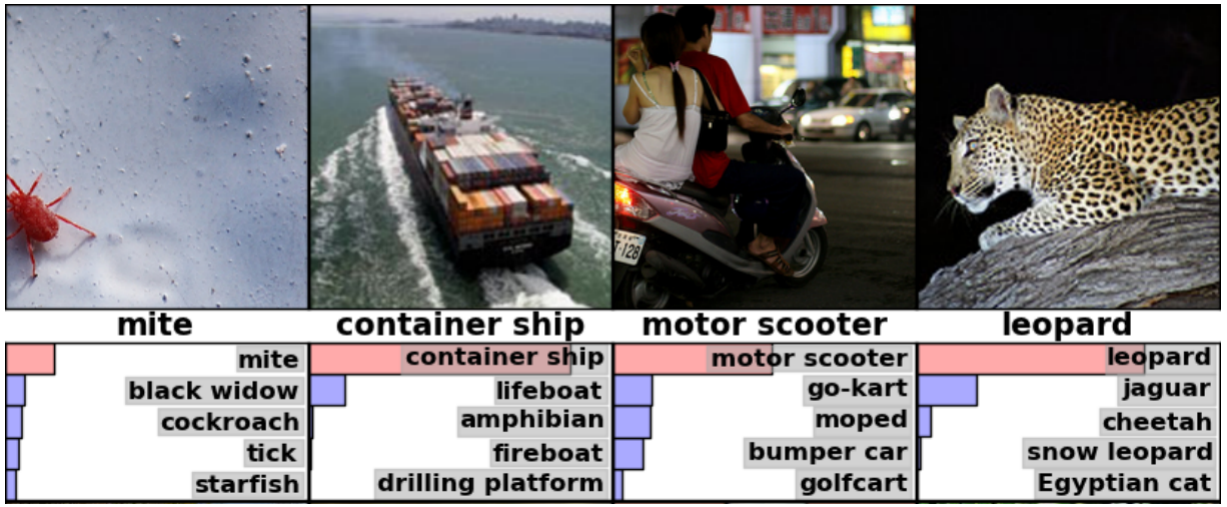
- It is faster (it’s pre-trained)
- It is cheaper (no need to have GPU farm)
- Achieve good accuracy

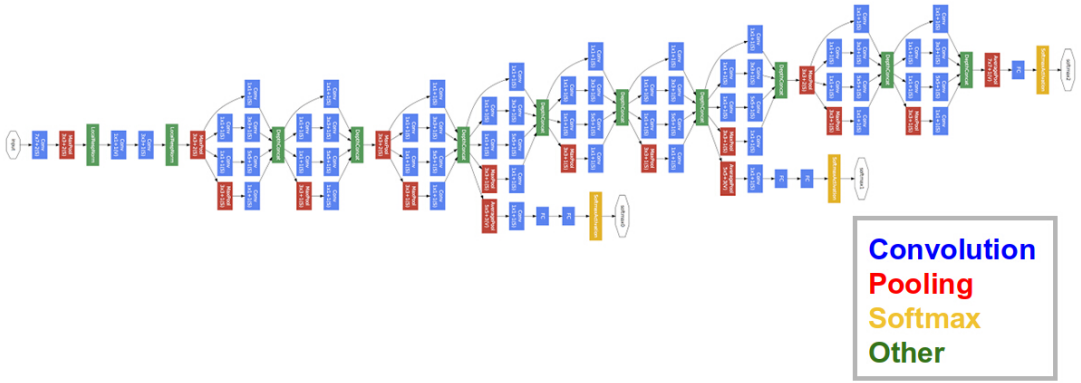
ImageNet

- ImageNet is an image database organized according to the WordNet hierarchy (currently only the nouns), in which each node of the hierarchy is depicted by hundreds and thousands of images.
- Currently there are over five hundred images on average per node.

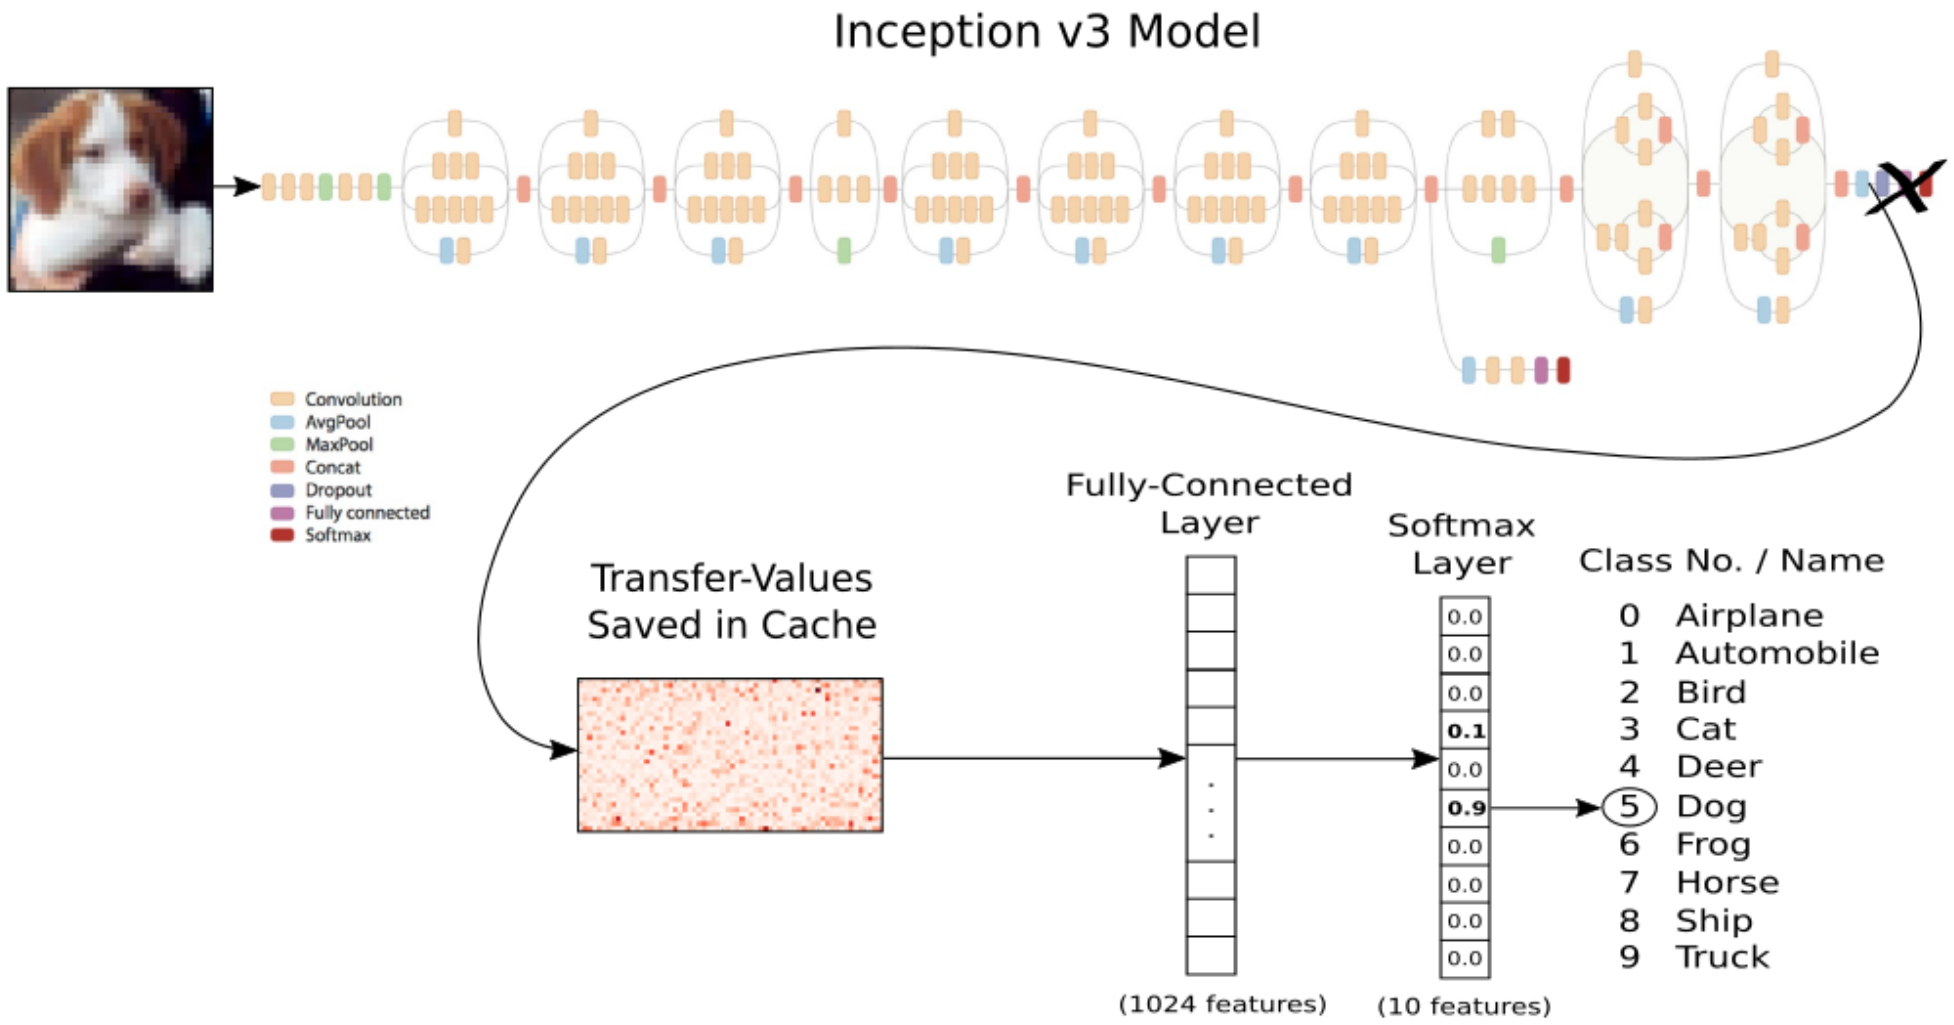
Inception V3

- Inception-v3 is trained for the ImageNet Large Visual Recognition Challenge using the data from 2012.
- This is a standard task in computer vision, where models try to classify entire images into 1000 classes, like "Zebra", "Dalmatian", and "Dishwasher".





Transfer Learning

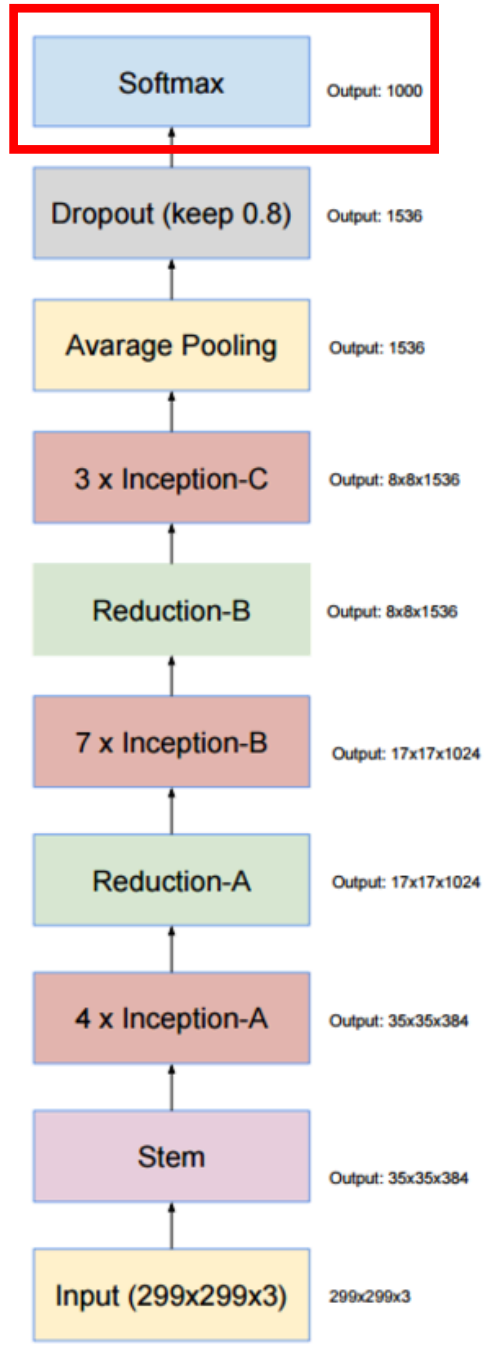


Transfer Learning

- Pre-trained model has learned to pick out features from images that are useful in distinguishing one image (class) from another.
- Initial layer filters encode edges and color, while later layer filters encode texture and shape.
- Cheaper to “transfer” that learning to new classification scenario than retrain a classifier from scratch.

Transfer Learning

- Remove the Fully Connected (Bottleneck layer) from pre-trained ImageNet Inception v3 model.
- Run images from Dataset through this truncated network to produce (semantic) image vectors.
- Use these vectors to train another classifier to predict the labels in training set.
- Prediction
  - Image needs to be preprocessed into image vector through truncated pre-trained ImageNet Inception v3 model.
  - Prediction made with second classifier against image vector



Further Fine Tuning...

- Remove bottleneck (classifier) layer from pre-trained network.
- Freeze all weights except the last (few) convolutional layers.
- Attach your own classifier to the bottom.
- Train the resulting classifier with very low learning rate.
- Computationally more expensive than Transfer Learning but still cheaper than training network from scratch.
- More robust model.

Transfer Learning with TensorFlow

- Transfer learning does not require GPUs to train
- Training across the training set (2,000 images) took less than a minute on my Macbook Pro without GPU support. This is not entirely surprising though, as the final model is just a softmax regression.
- With TensorBoard, it is able to provide summaries that make it easier to understand, debug, and optimize the retraining.
- It is also able visualize the graph and statistics, such as how the weights or accuracy varied during training.
- https://www.tensorflow.org/tutorials/image_retraining

Demo

Slides & Codes available from Github:

http://bit.ly/google-io-kl

Summary

- Possible to train very large models on small data by using transfer learning and domain adaptation
- Off the shelf features work very well in various domains and tasks
- Lower layers of network contain very generic features, higher layers more task specific features
- Supervised domain adaptation via fine tuning almost always improves performance

Thanks!
